

## General probability questions

1. Exercises 2E1 in the book.
2. Exercises 2E2 in the book.
3. Exercises 2E3 in the book.

## Bayes theorem

1. In this exercise we will use Bayes theorem for spell correction. Let  $\theta$  be the word one wanted to spell, and let  $Y$  be the word that is actually spelled, which in this case is '*radom*'. Suppose we know that it should be one of the three words  $\{'radom', 'random', 'radon'\}$ . The three words are not equally like a priori (unnormalized prior taken from frequency of the word occurring):

$\theta$	$P(\theta)$
' <i>random</i> '	$7 \times 10^{-5}$
' <i>radon</i> '	$7 \times 10^{-6}$
' <i>radom</i> '	$3 \times 10^{-7}$

The conditional probability of  $\theta$  given one has spelled '*radom*' (the likelihood) is, by Google spell checker, given by (again not normalized):

$\theta$	$P(Y = 'radom'   \theta)$
' <i>random</i> '	0.00193
' <i>radon</i> '	0.000143
' <i>radom</i> '	0.975

What is the posterior distribution of  $\theta$  given that  $Y = 'radom'$ ?

## Proportionality

Recall that two functions  $f_1(x)$  and  $f_2(x)$  are proportional,  $\propto$ , to each other if there exists a positive constant  $c > 0$  such that  $f_1(x) = cf_2(x)$ .

1. Suppose  $f(x) = e^{-x^2}$  which of the following functions are  $f(x)$  proportional to
  - a)  $f_1(x) = e^{-\frac{x^2}{2}}$ .
  - b)  $f_2(x) = e^{-(x-\mu)^2}$ .
  - c)  $f_3(x) = e^{-x^2-\mu^2}$ .
2. Suppose  $f(p) = \frac{1}{B(\alpha, \beta)} p^{\alpha-1} (1-p)^{\beta-1}$  which of the following functions are  $f(p)$  proportional to
  - a)  $f_1(p) = p^{\alpha-1} (1-p)^{\beta-1}$ .
  - b)  $f_2(p) = p^{\alpha+2-1} (1-p)^{\beta-1}$ .
  - c)  $f_3(p) = p^{\alpha-1} (1-p)^{\beta+3-1}$ .

## Independence

Independence recall that the definition of independence for probabilities is given by

$$P(A \cap B) = P(A)P(B).$$

The same holds for densities, i.e.

$$p_{X,Y}(x,y) = p_X(x)p_Y(y).$$

1. Suppose that the joint density of  $X_1$  and  $X_2$  given  $p$  is proportional to:

$$p(x_1, x_2|p) \propto p^{x_1+x_2}(1-p)^{2-x_1-x_2}$$

Show that given  $p$  that  $X_1$  and  $X_2$  two are independent.

2. Suppose we have a uniform prior on  $p$  (i.e.  $p(p) = 1$ ), and suppose we observe  $n$  independent observations of a Bernoulli random variable (i.e.  $p(X|p) = p^X(1-p)^{1-X}$ ). Show that (using Bayes theorem and independence)

$$p(p|X_1, X_2, \dots, X_n) \propto p^{\sum_{i=1}^n X_i} (1-p)^{n-\sum_{i=1}^n X_i}$$

## Distributions

A key concept in Bayesian modeling is distribution.

1. The most famous distribution is the Normal distribution:

$$p(x|\mu, \sigma) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}.$$

- a) Is the distribution of  $x$  continuous or discrete?
  - b) Suppose we want to put a prior on  $\mu$ , if we have no special information should the prior be continuous or discrete?
  - c) Suppose we want to put a prior on  $\sigma$ , if we have no special information should the prior be continuous or discrete? Should there be any other restriction on the domain of  $\sigma$  (which values  $\sigma$  can take)?
  - d) Write the integral form of  $P(X > 2|\mu = 2, \sigma = 4)$ .
2. An other classical distribution is the Poisson distribution:

$$p(x|\lambda) = \frac{\lambda^x e^{-\lambda}}{x!} \quad x = 0, 1, 2, \dots$$

- a) Is the distribution of  $x$  continuous or discrete?
- b) Suppose we want to put a prior on  $\lambda$ , if we have no special information should the prior be continuous or discrete?
- c) Write the sum form of  $P(X > 2|\lambda = 2)$

- d) Suppose we observe two independent observations  $(X_1, X_2)$  of  $p(x|\lambda)$ . Further assume an exponential prior on  $\lambda$  ( $p(\lambda) \propto e^{-\beta\lambda}$ ). Use Bayes theorem and independence to derive the posterior distribution of  $\lambda$  ( $p(\lambda|X_1, X_2)$ )

Hint: For the normalizing constant note that the density of the Gamma distribution is given by

$$f(x|a, b) = \frac{b^a}{\Gamma(a)} x^{a-1} e^{-bx}$$

## Bayesian models

- 4E1
- 4E2
- 4E3
- 4E4
- 4E5
- In the model definition below, which line is the prior:

$$\begin{aligned} y &\sim \text{Poisson}(\lambda) \\ \lambda &\sim \text{exp}(\alpha) \end{aligned}$$

- 4M2
- 4M3
- Translate the mao model below into a mathematical definition.

```
flist <- alist(
  height ~ dpois(mu),
  mu      = exp(a + b * x),
  a       ~ dnorm(0, 20),
  b       ~ dnorm(0, 20)
)
```
